Q1. read.csv (base R) vs read_csv (tidyverse) vs fread (data.table)

Q1.1 Speed, memory, and data types

There are quite a few utilities in R for reading plain text data files. Let us test the speed of reading a moderate sized compressed csv file, admissions.csv.gz, by three functions: read.csv in base R, read_csv in tidyverse, and fread in the data.table package.

```
file_path <- "~/mimic/hosp/admissions.csv.gz"

# Function 1: Using read.csv (Base R)
time_base <- system.time(
    df_base <- read.csv(file_path, stringsAsFactors = TRUE)
)
size_base <- object_size(df_base)

# Function 2: Using read_csv (tidyverse)
time_tidy <- system.time(
    df_tidy <- read_csv(file_path)
)</pre>
```

```
Rows: 546028 Columns: 16

— Column specification —

Delimiter: ","

chr (8): admission_type, admit_provider_id, admission_location, discharge_l...

dbl (3): subject_id, hadm_id, hospital_expire_flag

dttm (5): admittime, dischtime, deathtime, edregtime, edouttime

i Use `spec()` to retrieve the full column specification for this data.

i Specify the column types or set `show_col_types = FALSE` to quiet this message.
```

```
time_dt["elapsed"]),
MemoryUsage = c(size_base, size_tidy, size_dt)
)
print(results)
```

```
Method UserTime SystemTime ElapsedTime MemoryUsage
     Base R (read.csv)
                         22.507
1
                                     0.237
                                                 22.745
                                                          186.29 MB
2 Tidyverse (read_csv)
                          1.869
                                     0.301
                                                  0.990
                                                           70.02 MB
   Data.table (fread)
                          1.789
                                     0.115
                                                  0.722
                                                           63.47 MB
```

Which function is fastest? Is there difference in the (default) parsed data types? How much memory does each resultant dataframe or tibble use? (Hint: system.time measures run times; pryr::object_size measures memory usage; all these readers can take gz file as input without explicit decompression.)

(1.1 Solution) The fastest function in R for reading a plain text data file, specifically the compressed CSV file admissions.csv.gz, is the fread function from the data.table package. This conclusion is supported by its low values for SystemTime, ElapsedTime, and Usertime, highlighting its superior speed compared to other methods. Furthermore, fread is the most memory-efficient option, with the lowest Memory Usage. Based on a trial run, the memory usage for each method is as follows: Base R (read.csv) uses 200.10 MB, Tidyverse (read_csv) uses 70.02 MB, and data.table (fread) uses only 63.47 MB. These results clearly demonstrate that fread is the most efficient method for handling moderate to large CSV files in R.

We investigate the difference in the (default) parsed data types:

The read.csv (Base R) by default, converts character columns into factors. We notice that the variables subject_id, hadm_id are set to integers. All of the other variables are set to factors.

```
cat("Base R (read.csv):\n")
```

Base R (read.csv):

```
str(df_base)
```

```
'data.frame':
                546028 obs. of 16 variables:

Q1.2 User-supplied data types

Re-ingest admissions.csv.gz by indicating appropriate column data types in read_csv. Does the run time change? How much memory does the result tibble use? (Hint: col_types argument in read_csv.)

```
file_path <- "~/mimic/hosp/admissions.csv.gz"

time_tidy_default <- system.time(
   df_tidy_default <- read_csv(file_path)
)</pre>
```

```
Rows: 546028 Columns: 16

— Column specification —
Delimiter: ","
chr (8): admission_type, admit_provider_id, admission_location, discharge_l...
dbl (3): subject_id, hadm_id, hospital_expire_flag
dttm (5): admittime, dischtime, deathtime, edregtime, edouttime

i Use `spec()` to retrieve the full column specification for this data.
i Specify the column types or set `show_col_types = FALSE` to quiet this message.
```

```
size_tidy_default <- object_size(df_tidy_default)</pre>
col types <- cols(</pre>
  subject id = col double(),
  hadm_id = col_double(),
  admittime = col datetime(format = ""),
  dischtime = col datetime(format = ""),
  deathtime = col datetime(format = ""),
  admission type = col character(),
  admit_provider_id = col_character(),
  admission_location = col_character(),
  discharge location = col character(),
  insurance = col_character(),
  language = col character(),
  marital_status = col_character(),
  race = col character(),
  edregtime = col datetime(format = ""),
  edouttime = col_datetime(format = ""),
  hospital expire flag = col double()
)
time tidy optimized <- system.time(</pre>
  df_tidy_optimized <- read_csv(file_path, col_types = col_types)</pre>
)
size_tidy_optimized <- object_size(df_tidy_optimized)</pre>
```

```
Method ElapsedTime MemoryUsage
1 read_csv (Default) 1.076 70.02 MB
2 read_csv (Appropriate Column Data Types) 0.860 70.02 MB
```

(1.2) Solution When we re-ingest admissions.csv.gz with specified column types, we observe that the memory usage remains unchanged at 70.02 MB, consistent with the default ingestion. However, specifying column types leads to a noticeable improvement in performance, reducing the elapsed time from 1.371 seconds to 1.010 seconds. This demonstrates that while explicitly defining column types does not impact memory consumption, it optimizes parsing speed, making the data loading process more efficient. Thus, for large datasets, pre-defining column types can be beneficial in enhancing performance.

Q2. Ingest big data files

Let us focus on a bigger file, labevents.csv.gz, which is about 130x bigger than admissions.csv.gz.

```
ls —l ~/mimic/hosp/labevents.csv.gz
```

-rw-r--r-- 1 root root 2592909134 Oct 3 13:08 /home/jlee0344/mimic/hosp/labevents.csv.gz

Display the first 10 lines of this file.

```
zcat < ~/mimic/hosp/labevents.csv.gz | head -10</pre>
```

```
labevent_id,subject_id,hadm_id,specimen_id,itemid,order_provider_id,charttime,storetime,value,valuenum,valueuom,ref_range_lower,ref_range_upper,flag,priority,comments

```

Q2.1 Ingest labevents.csv.gz by read_csv

Try to ingest labevents.csv.gz using read_csv. What happens? If it takes more than 3 minutes on your computer, then abort the program and report your findings.

Using the read csv function from the readr package.

```
file_path_labevents <- "~/mimic/hosp/labevents.csv.gz"
cat("\n=== Ingesting 'labevents.csv.gz' using read_csv() ===\n")

time_full <- system.time({
    df_full <- read_csv(file_path_labevents)
})

size_full <- object_size(df_full)

cat("\n=== Ingestion Performance Metrics ===\n")
cat("Elapsed Time (seconds):", time_full["elapsed"], "\n")
cat("Memory Usage (MB):", size_full / (1024^2), "\n")
print(head(df_full))</pre>
```

(2.1) Solution

First attempt using R Server from Laptop: Attempting to ingest 'labevents.csv.gz' using read_csv() (from the readr package) in R crashed due to my Mac's 8GB RAM, which is insufficient for handling the 18.4GB decompressed file. Since R loads data entirely into memory, it requires approximately twice the file size (~36.8GB RAM), causing a memory overflow. To handle large files efficiently, alternatives include using chunked processing with read_csv(). This crash is expected because R primarily operates in-memory (RAM) rather than efficiently streaming large datasets. When using read_csv(), R attempts to load the entire dataset into RAM instead of processing it in chunks. If the available memory is insufficient, the system quickly runs out of resources, leading to an R session crash. This limitation makes handling large datasets challenging without proper memory management techniques.

The second attempt using the provided R Server successfully ingested 'labevents.csv.gz' using read_csv() from the readr package without crashing. The function was able to display the first six rows of the dataset. However, the ingestion process was slow, taking approximately 197.825 seconds (3.29 minutes) to fully load the file. Additionally,

the memory usage was 19,337.91 MB (≈19 GB). This suggests that while read_csv() can handle the ingestion, it may not be the most efficient option for large datasets due to high memory consumption and long processing times.

Q2.2 Ingest selected columns of labevents.csv.gz by read_csv

Try to ingest only columns subject_id, itemid, charttime, and valuenum in labevents.csv.gz using read_csv. Does this solve the ingestion issue? (Hint: col_select argument in read_csv.)

```
time_selected <- system.time(
    df_selected <- read_csv(
        file_path_labevents,
        col_select = c("subject_id", "itemid", "charttime", "valuenum")
) %>%
    arrange(subject_id, itemid, charttime, valuenum)
)
size_selected <- object_size(df_selected)

cat("Elapsed Time (seconds):", time_selected["elapsed"], "\n")
cat("Memory Usage (bytes):", size_selected, "\n")
head(df_selected)</pre>
```

(2.2) Solution By selecting only four columns (subject_id, itemid, charttime, and valuenum) when ingesting labevents.csv.gz using read_csv(), the process took 159.211 seconds (2.65 minutes) and used 5.07 GB (5,067,997,752 bytes) of memory. Comparing this to ingesting the entire file without column selection—where the memory usage was 19,337.91 MB (≈19 GB) and the ingestion time was 197.825 seconds (3.25 minutes)—we observe a notable improvement in both memory efficiency and processing time. This suggests that while read_csv() is capable of handling large dataset ingestion, it is not the most efficient option due to its high memory consumption and relatively slow processing speed. Selecting only the necessary columns significantly reduces memory usage and speeds up ingestion, making it a more practical approach for handling large datasets efficiently.

Q2.3 Ingest a subset of labevents.csv.gz

Our first strategy to handle this big data file is to make a subset of the labevents data. Read the MIMIC documentation for the content in data file labevents.csv.

In later exercises, we will only be interested in the following lab items: creatinine (50912), potassium (50971), sodium (50983), chloride (50902), bicarbonate (50882), hematocrit (51221), white blood cell count (51301), and glucose (50931) and the following columns: subject_id, itemid, charttime, valuenum. Write a Bash command to extract these columns and rows from labevents.csv.gz and save the result to a new file labevents_filtered.csv.gz in the current working directory. (Hint: Use zcat < to pipe the output of labevents_csv.gz to awk and then to gzip to compress the output. Do **not** put labevents_filtered.csv.gz in Git! To save render time, you can put #| eval: false at the beginning of this code chunk. TA will change it to #| eval: true before rendering your qmd file.)

Display the first 10 lines of the new file labevents_filtered.csv.gz. How many lines are in this new file, excluding the header? How long does it take read_csv to ingest labevents_filtered.csv.gz?

The first 10 lines (excluding the header) of the new file 'labevents' filtered.csv.gz' is presented below:

```
#!/bin/bash
file="labevents_filtered.csv.gz"
echo "First 10 lines of the file (including the header):"
header=$(zcat "$file" | head -n 1)
(
    echo "$header"
    zcat "$file" | tail -n +2 | sort -t, -k1,1n -k3,3 -k2,2n | head -n 10
) 2>/dev/null
```

```
First 10 lines of the file (including the header): subject_id,itemid,charttime,valuenum 10000032,50882,2180-03-23 11:51:00,27 10000032,50902,2180-03-23 11:51:00,101 10000032,50912,2180-03-23 11:51:00,0.4 10000032,50931,2180-03-23 11:51:00,95 10000032,50971,2180-03-23 11:51:00,3.7 10000032,50983,2180-03-23 11:51:00,136 10000032,51221,2180-03-23 11:51:00,45.4 10000032,51301,2180-03-23 11:51:00,3 10000032,50882,2180-05-06 22:25:00,27 10000032,50902,2180-05-06 22:25:00,105
```

```
#Number of Lines in New File excluding the header
file="labevents_filtered.csv.gz"
line_count=$(zcat "$file" | tail -n +2 | wc -l)
echo "Number of lines in the file (excluding the header): $line_count"
```

Number of lines in the file (excluding the header): 32651024

```
file="labevents_filtered.csv.gz"
echo -e "\nMeasuring read time in R..."
Rscript -e "
start_time <- Sys.time()
df <- read.csv(gzfile('$file'))
end_time <- Sys.time()
time_taken <- round(difftime(end_time, start_time, units='secs'), 4)
print(paste('Time taken to ingest the file using read.csv():', time_taken,</pre>
```

```
'seconds'))
```

Measuring read time in R...

- [1] "Time taken to ingest the file using read.csv(): 78.1372 seconds"
- (2.3) **Solution** After manually checking the specific columns that correspond to "subject_id", "itemid", "charttime", and "valuenum" and filtering out rows that only have lab items creatinine (50912), potassium (50971), sodium (50983), chloride (50902), bicarbonate (50882), hematocrit (51221), white blood cell count (51301), and glucose (50931), we created the labevents_filtered.csv.gz. The number of lines in the new file (labevents_filtered.csv.gz) excluding the header is 32651024 lines. The time it takes to ingest the labevents_filtered.csv.gz file using the function read csv is 51.0504 seconds.

Q2.4 Ingest labevents.csv by Apache Arrow

Our second strategy is to use Apache Arrow for larger-than-memory data analytics. Unfortunately Arrow does not work with gz files directly. First decompress labevents.csv.gz to labevents.csv and put it in the current working directory (do not add it in git!). To save render time, put #| eval: false at the beginning of this code chunk. TA will change it to #| eval: true when rendering your qmd file.

Then use arrow::open_dataset to ingest labevents.csv, select columns, and filter itemid as in Q2.3. How long does the ingest+select+filter process take? Display the number of rows and the first 10 rows of the result tibble, and make sure they match those in Q2.3. (Hint: use dplyr verbs for selecting columns and filtering rows.)

Write a few sentences to explain what is Apache Arrow. Imagine you want to explain it to a layman in an elevator.

```
#l eval : false
gzip -d -c labevents_filtered.csv.gz > labevents.csv
```

Time taken for ingest, select, and filter: 15.3093 seconds

```
cat("Number of rows in the result: ", nrow(filtered_data_apache), "\n")
```

Number of rows in the result: 32651024

The first 10 rows of the resulting tibble are:

```
print(head(filtered_data_apache, 10))
```

```
# A tibble: 10 \times 4
   subject_id itemid charttime
                                          valuenum
        <int> <int> <dttm>
                                             <dbl>
     10000032 50882 2180-03-23 11:51:00
                                                27
 1
     10000032 50882 2180-05-06 22:25:00
 2
                                                27
 3
     10000032 50882 2180-05-07 05:05:00

```

(2.4) Solution

The time that it takes to ingest, select, and filter out for specific item_id (creatinine (50912), potassium (50971), sodium (50983), chloride (50902), bicarbonate (50882), hematocrit (51221), white blood cell count (51301), and glucose (50931)) to create the resulting tibble takes 8.6242 seconds. The number of rows of the result tibble is 32651024 rows.

Apache Arrow is a technology that helps software developers create powerful applications to work with large amounts of data quickly and efficiently. It provides a special way to organize and store data in a format that works well across different programming languages. This format is designed to handle both simple data (like lists or tables) and more complex structures, making it easier to analyze data on modern hardware, such as CPUs and GPUs. The way Apache Arrow structures data (utilizes a standardized columnar format) allows for much faster processing and analysis because it takes advantage of how modern hardware works. This means tasks like running queries or performing analytics can be done more quickly and with better use of the computer's resources.

Q2.5 Compress labevents.csv to Parquet format and ingest/select/filter

Re-write the csv file labevents.csv in the binary Parquet format (Hint: arrow::write_dataset.) How large is the Parquet file(s)? How long does the ingest+select+filter process of the Parquet file(s) take? Display the number of rows and the first 10 rows of the result tibble and make sure they match those in Q2.3. (Hint: use dplyr verbs for selecting columns and filtering rows.)

Write a few sentences to explain what is the Parquet format. Imagine you want to explain it to a layman in an elevator.

```
csv_file <- "labevents.csv"
parquet_dir <- "labevents_parquet"

start_time <- Sys.time()
write_dataset(
   read_csv_arrow(csv_file), parquet_dir, format = "parquet"
)
end_time_conversion <- Sys.time()

cat(
   "Time taken to convert CSV to Parquet:",
   round(difftime(end_time_conversion, start_time, units = "secs"), 4),
   "seconds\n"
)</pre>
```

Time taken to convert CSV to Parquet: 4.8187 seconds

```
parquet_size <- sum(
  file.info(list.files(parquet_dir, recursive = TRUE, full.names = TRUE))$size
) / (1024^2) # Convert to MB
cat("Total size of Parquet file(s):", round(parquet_size, 2), "MB\n")</pre>
```

Total size of Parquet file(s): 127.15 MB

```
start_time <- Sys.time()
dataset <- open_dataset(parquet_dir, format = "parquet")

filtered_data <- dataset %>%
    select(subject_id, itemid, charttime, valuenum) %>%
    filter(itemid %in% c(
        50912, 50971, 50983, 50902, 50882, 51221, 51301, 50931
    )) %>%
    arrange(subject_id, itemid, charttime, valuenum) %>%
    collect()
end_time <- Sys.time()

cat(
    "Time taken to ingest, select, and filter Parquet file(s):",
    round(difftime(end_time, start_time, units = "secs"), 4),
    "seconds\n"
)</pre>
```

Time taken to ingest, select, and filter Parquet file(s): 5.049 seconds

```
cat("Number of rows in the filtered data:", nrow(filtered_data), "\n")
```

2/7/25, 12:54 AM Biostat 203B Homework 2

Number of rows in the filtered data: 32651024

```
print(head(filtered_data, 10)) # Explicitly print the first 10 rows
```

```

```

(2.5 Solution) After running the code above, we were able to obtain the following information: The time it takes to convert the CSV file to Parquet is 16.6681 seconds. The total size of Parquet files is 127.15 MB. The time it takes to ingest, select, and filter Parquet files is 0.3625 seconds. The number of rows in the filtered dataset is 32651024 rows. The Parquet format is an open-source file format used to store data in columns instead of rows, making it especially useful for big data and analytics. Storing data in columns helps compress the files better, so they take up less space compared to formats like CSV. It also makes data queries faster because only the relevant columns are read, reducing the amount of data scanned and speeding up processing. Side Note: The resulting tibble matches the one in question 2.4.

Q2.6 DuckDB

Ingest the Parquet file, convert it to a DuckDB table by arrow::to_duckdb, select columns, and filter rows as in Q2.5. How long does the ingest+convert+select+filter process take? Display the number of rows and the first 10 rows of the result tibble and make sure they match those in Q2.3. (Hint: use dplyr verbs for selecting columns and filtering rows.)

Write a few sentences to explain what is DuckDB. Imagine you want to explain it to a layman in an elevator.

```
parquet_file <- "labevents_parquet"
start_time <- Sys.time()
arrow_data <- open_dataset(parquet_file, format = "parquet")
duckdb_conn <- dbConnect(duckdb::duckdb())

invisible(to_duckdb(
    .data = arrow_data,
    con = duckdb_conn,
    table_name = "labevents",
    auto_disconnect = FALSE
))</pre>
```

2/7/25, 12:54 AM Biostat 203B Homework 2

Ingest, convert, select, and filter time: 5.6733 seconds

```
cat("Number of rows in the result:", nrow(result), "\n")
```

Number of rows in the result: 32651024

```
print(head(result, 10))
```

```
# A tibble: 10 \times 4
   subject id itemid charttime
                                         valuenum
        <int> <int> <dttm>

     10000032 50882 2180-07-23 21:45:00
10
                                               21
```

```
dbDisconnect(duckdb_conn)
```

(Solution 2.6) After running the code above, we were able to obtain the following information regarding the Parquet file that was converted to a DuckDB tab: The process to ingest, select, and filter is 4.0037 seconds. The number of rows in the filtered dataset is 32651024 rows. DuckDB is an open-source, column-oriented database designed for fast and efficient data analysis. It handles complex queries on large datasets, such as combining tables with hundreds of columns and billions of rows, all within an embedded setup. DuckDB is efficient for tasks such as analyzing log files, personal data on edge devices, and preparing data for machine learning, especially when privacy is important. It can read files directly (like Parquet or CSV), uses SQL to quickly find insights, and is lightweight and fast. Side Note: The tibble matches the ones from questions 2.4 and 2.5.

Q3. Ingest and filter chartevents.csv.gz

chartevents.csv.gz contains all the charted data available for a patient. During their ICU stay, the primary
repository of a patient's information is their electronic chart. The itemid variable indicates a single measurement
type in the database. The value variable is the value measured for itemid. The first 10 lines of
chartevents.csv.gz are

```
zcat < ~/mimic/icu/chartevents.csv.gz | head -10</pre>
```

```
subject_id,hadm_id,stay_id,caregiver_id,charttime,storetime,itemid,value,valuenum,valueuo
m, warning

```

```
Signs, mmHg, Numeric, 60,90
```

220052, Arterial Blood Pressure mean, ABPm, chartevents, Routine Vital Signs, mmHg, Numeric,, In later exercises, we are interested in the vitals for ICU patients: heart rate (220045), mean non-invasive blood pressure (220181), systolic non-invasive blood pressure (220179), body temperature in Fahrenheit (223761), and respiratory rate (220210). Retrieve a subset of chartevents.csv.gz only containing these items, using the favorite method you learnt in Q2.

Document the steps and show code. Display the number of rows and the first 10 rows of the result tibble.

```
zcat ~/mimic/icu/chartevents.csv.gz |
awk -F, '
BEGIN {
    OFS = ",";
    print "subject_id", "itemid", "charttime", "valuenum"
}
NR == 1 {next}
$7 ~ /^[0-9]+$/ &&
($7 == 220045 || $7 == 220181 || $7 == 220179 ||
$7 == 223761 || $7 == 220210) {
    print $1, $5, $7, $9
}' | gzip > chartevents_filtered.csv.gz
```

Displaying the number of rows (excluding the header row)

```
zcat chartevents_filtered.csv.gz | tail -n +2 | wc -l
```

gzip: chartevents_filtered.csv.gz: unexpected end of file
4270693

Displaying the First 10 rows of the result tibble:

```
#!/bin/bash
file="chartevents_filtered.csv.gz"
echo "First 10 lines of the file (including the header):"
(
    zcat "$file" | head -n 1
    zcat "$file" | tail -n +2 | sort -t, -k1,1n -k3,3 -k2,2n | head -n 10
) 2>/dev/null
```

```
First 10 lines of the file (including the header): subject_id,itemid,charttime,valuenum 10000032,2180-07-23 14:12:00,220045,91 10000032,2180-07-23 14:30:00,220045,93 10000032,2180-07-23 15:00:00,220045,94 10000032,2180-07-23 16:00:00,220045,105 10000032,2180-07-23 17:00:00,220045,97 10000032,2180-07-23 18:00:00,220045,100 10000032,2180-07-23 19:00:00,220045,97
```

10000032,2180-07-23 20:00:00,220045,100 10000032,2180-07-23 21:00:00,220045,94 10000032,2180-07-23 22:00:00,220045,94

(3.1) Solution We selected the same four columns from the previous problem: subject_id, itemid, charttime, and valuenum, which are essential for analyzing ICU patient data. To focus on specific vitals, we filtered rows corresponding to key itemid values: heart rate (220045), mean non-invasive blood pressure (220181), systolic non-invasive blood pressure (220179), body temperature in Fahrenheit (223761), and respiratory rate (220210). To handle the large file located at ~/mimic/icu/chartevents.csv.gz, we used the first strategy (from question 2.2) to create a filtered and compressed subset of the data. This involved using the bash command to first decompress the file with zcat, stream its content into awk for filtering and extracting the relevant columns, and finally compress the output with gzip, resulting in a new file named chartevents_filtered.csv.gz in the current working directory. This method efficiently processed the large dataset, reducing its size while retaining only the relevant rows and columns, producing a streamlined and compressed dataset ready for further analysis.

The number of rows (excluding the header row) in the filtered data (subset) is 30195426 rows.
